 Abstract statement of the problem

If $B(\cdot)$ is essentially bounded (i.e. if $B(\cdot)$ belongs to $L^{\infty}([0,\tau]; \mathscr{L}(X,\mathscr{H})))$, then the solution of

$$rac{\partial}{\partial t}T = (c^2\Delta + \mathbf{a}(x,y)\cdot
abla)T + B(t)\eta(t);$$

 $T(0,x,y) = T_0(x) + \xi$

is a stochastic process with values in $\mathscr{H} = L^2(\Omega)$.

Stationary and Mobile Sensors

Suppose that we can only "measure" $T(t, \mathbf{x})$ with a finite number of sensors. We will consider two ways of doing this:

Stationary Networks The position of the sensor remains constant. The design variables are the positions of the sensors in the domain.

The system Possible measurements Types of Mobile and Stationary Sensors Abstract statement of the problem What is our criteria?

Stationary and Mobile Sensors

Suppose that we can only "measure" $T(t, \mathbf{x})$ with a finite number of sensors. We will consider two ways of doing this:

Stationary Networks The position of the sensor remains constant. The design variables are the positions of the sensors in the domain.

Mobile Networks The positions of the sensors are described by controlled differential equations and their initial positions are **fixed**. The design variable are the controls.

イロト イポト イヨト

The system Possible measurements Types of Mobile and Stationary Sensors Abstract statement of the problem What is our criteria?

Suppose we have a finite number of mobile sensors.

イロト イヨト イヨト イヨト

E

Suppose we have a finite number of mobile sensors. The position of the sensors are given by smooths trajectories $\hat{\mathbf{x}}_1(t), \hat{\mathbf{x}}_2(t), \dots, \hat{\mathbf{x}}_N(t)$, inside Ω that are determined by the controlled ordinary differential equations

$$\dot{\hat{\mathbf{x}}}_i = f_i(\hat{\mathbf{x}}_1, \hat{\mathbf{x}}_2, \dots, t, u),$$

with $|u(t)| \leq 1$

Suppose we have a finite number of mobile sensors. The position of the sensors are given by smooths trajectories $\hat{\mathbf{x}}_1(t), \hat{\mathbf{x}}_2(t), \dots, \hat{\mathbf{x}}_N(t)$, inside Ω that are determined by the controlled ordinary differential equations

$$\dot{\hat{\mathbf{x}}}_i = f_i(\hat{\mathbf{x}}_1, \hat{\mathbf{x}}_2, \dots, t, u),$$

with $|u(t)| \leq 1$. So, we may assume that each sensor measures an average value of $T(t, \mathbf{x})$ within a fixed range δ of the position of the sensor for each $t = [0, \tau]$

Suppose we have a finite number of mobile sensors. The position of the sensors are given by smooths trajectories $\hat{\mathbf{x}}_1(t), \hat{\mathbf{x}}_2(t), \dots, \hat{\mathbf{x}}_N(t)$, inside Ω that are determined by the controlled ordinary differential equations

 $t \mapsto \Sigma(t)$ is trace class continuous Existence of Minimizers

The Riccati integral equation

We are interested in trace-class valued solutions of

$$\Sigma(t) = T(t)\Sigma_0 T^*(t) + \int_0^t T(t-s)(BB^* - \Sigma(C^*C)\Sigma)(s)T^*(t-s)ds,$$

where the integral is well defined as a Bochner integral, so the solution is a "uniform" one.

 $t \mapsto \Sigma(t)$ is trace class continuous Existence of Minimizers

The Riccati integral equation

We are interested in trace-class valued solutions of

$$\Sigma(t) = T(t)\Sigma_0 T^*(t) + \int_0^t T(t-s)(BB^* - \Sigma(C^*C)\Sigma)(s)T^*(t-s)ds,$$

where the integral is well defined as a Bochner integral, so the solution is a "uniform" one.

This is not the usual case, for example if T(t) is semigroup of linear operators with generator A,

$$\int_0^1 T(t) \,\mathrm{d}t,$$

is a well defined Bochner integral IF AND ONLY IF A is bounded!

, and $\mathbf{x} = (x, y) \in \Omega \equiv (0, 1) \times (0, 1)$. With $T(t, \mathbf{x})\Big|_{x \in \partial \Omega} = 0$ and $T(0, x) = T_0(x)$.
In this example

$$b(x, y, r) = 10 + 40e^{-r\left((x-0.1)^2 + (y-0.1)^2\right)}$$
$$c(\mathbf{x} - \mathbf{y}) = e^{-20\left((x_1 - y_1)^2 + (x_2 - y_2)^2\right)}$$

Then, it appears that we have to move the sensor uniformly along $x_0 + x_1 \simeq 1$ to minimize the functional.

イロト イヨト イヨト イヨト

Then, it appears that we have to move the sensor uniformly along $x_0 + x_1 \simeq 1$ to minimize the functional. Apparently the minimum is attained when $x_0 \simeq 0.592$ and $x_1 \simeq 0.590$... which is more or less stationary.

The sensors

Assume we have 3 sensors located at the points (0.6, 0.4), (0.5, 0.5) and (0.4, 0.6) and their trajectories are given by the equations

$$\vec{x}_i(t, u) = \begin{pmatrix} x_i^0 \\ y_i^0 \end{pmatrix} + \int_0^t e^{\mathbf{A}(t-s)} \mathbf{b} u_i(s) \, \mathrm{d}s$$

where

$$\mathbf{A} = \left(\begin{array}{cc} -1 & 0.3 \\ 0 & -1 \end{array}\right) \qquad \text{ and } \qquad \mathbf{b} = \left(\begin{array}{c} 1.5 \\ -1 \end{array}\right).$$

Steepest Descent Method

We will use a gradient descent method to try to compute a local minimizer of the problem.

- Start with the control with some choice $u^0(t) = (u_1^0(t), u_2^0(t), u_2^0(t)).$
- Opdate the control as

$$u^{n+1}(t) = u^n(t) - \alpha_n J'(u^n)(t),$$

where J'(u) is the gradient of J at u and α_n is chosen if possible as

$$\alpha_n = \arg \min_{\alpha} J(u^n - \alpha J'(u^n)),$$

and stop if $J(u^{n+1})$ is not decreased by at least 2% with respect to $J(u^n)$.
